

CHAPTER 5

Chip Seal Materials Selection

The performance of a chip seal is largely dependent on the materials used. Therefore, selecting the appropriate aggregates and asphalt emulsion and deciding whether to apply a fog seal to the surface play a significant role in the success of the project. The following discussion provides guidance regarding these factors.

5.1 Chip Gradation

The gradation of the chip should be one- or two-sized, but the maximum size should be selected based on traffic volume, pavement texture, and the required level of sealing. Generally, larger aggregate provides greater ability to seal because of the higher volume of binder required to hold the chips in place, and depending on traffic volume, provides longer life expectancy. However, larger aggregates increase the chances for vehicle damage, noise, and roughness.

5.2 Modified or Unmodified Emulsion

Modified emulsions usually refer to some sort of elastomeric polymer or rubber added to the emulsion or to the base asphalt binder prior to emulsification. Because modified emulsions should offer greater adhesivity and potentially shorter time required before opening to traffic, they are generally used on higher traffic pavements, where vehicle damage potential is

greater and where limited time under traffic control is usually desirable.

5.3 Fog Seal After Chip Seal

A fog seal may be applied to any completed chip seal as a means of providing a high color contrast for paint stripes. There are also some preliminary indications that the fog seal provides some additional waterproofing (Shuler 2007). Care should be taken whenever applying a fog seal since pavement friction could be reduced if the fog seal is applied at too high an application rate, the fog seal emulsion has a high residue content, or the fog seal has not broken sufficiently to support uncontrolled traffic.

5.4 Emulsion-Aggregate Compatibility

There is anecdotal evidence of apparent incompatibility arising from use of anionic or cationic emulsions with siliceous or calcareous aggregates, respectively. This incompatibility manifests itself with a loss of aggregate from the chip seal. This behavior was not observed during the NCHRP Project 14-17 research, in which 20 combinations of aggregates and emulsions were represented. Therefore, unless impractical, anionic emulsions should be paired with positively charged aggregates (i.e., calcareous), and cationic emulsions should be matched with negatively charged aggregates (i.e., siliceous) to avoid possible incompatibility between the materials.

Quantifying the Benefits of Improved Rolling of Chip Seals Y. Richard Kim, 2008 This report presents an improvement in the rolling protocol for chip seals based on an evaluation of aggregate retention performance and aggregate embedment depth The flip over test FOT Vialit test modified sand circle test digital image processing technique and the third scale Model Mobile Loading Simulator MMLS3 are employed to evaluate the effects of the various rolling parameters and to measure chip seal performance The samples used to evaluate the chip seal rolling protocol were obtained directly from field construction In order to determine the optimal rolling protocol the effects of roller type number of coverages coverage distribution on the sublayers of a multiple chip seal i e the split seal and triple seal and rolling pattern are evaluated using the results of aggregate retention performance tests the modified sand circle method and the digital image process It is found that two types of roller the pneumatic tire roller and the combination roller are recommended as the optimal rollers for the chip seal In addition it is found that the optimal number of coverages for the chip seal is three coverages Moreover the performance of the triple seal without coverage at the bottom layer does not affect the aggregate retention performance although the split seal does require coverage at the bottom layer Finally it is found from the MMLS3 results that the delayed rolling time between the spreading of the aggregate and the initial rolling significantly affects the aggregate loss and that the delayed rolling time is related to the aggregate moisture condition and the ambient temperature Effects of different rolling patterns are investigated based on the delayed rolling time and roller speeds and recommendations are developed for two and three roller scenarios *Transearch*, 1991 **Haynes GM N-Cars Owners Workshop Manual, No. 1420** Bob Henderson, J.
