

CONCLUSIONS

This synthesis identified technologies and practices available to transportation agencies for utilization of rock-socketed drilled shafts as reliable and cost-effective structure foundations. All thirty-two of the state transportation agencies responding to the survey are currently using rock-socketed shafts, some quite extensively (more than 20 projects per year). The single Canadian agency responding to the survey has not used drilled shafts extensively to date. Use of rock-socketed drilled shafts for transportation structures has increased significantly over the past 25 years and technologies applied to design, construction, and testing have advanced considerably.

The design process for structural foundations by state transportation agencies is outlined in chapter one. Responsibilities typically are separated into geotechnical and structural categories. Site characterization, geomaterial property evaluation, and design issues related to geotechnical capacity or load-deformation analysis are normally addressed as geotechnical issues, whereas structural modeling and reinforced-concrete design are normally carried out by structural engineers. Design for lateral loading requires significant input and analysis by both geotechnical and structural personnel.

The overall process of design and construction (i.e., engineering) is shown to consist of highly interrelated factors, requiring an integrated approach to drilled shaft foundations. Figure 3 in chapter one illustrates the process in the form of a flowchart. Adequate site characterization is needed to obtain the basic information required for both geotechnical analysis and construction. Constructability issues are best addressed during the design process, when decisions such as whether to include side resistance, base resistance, or both must be made on the basis of anticipated subsurface conditions, construction methods, load testing, inspection methods, and experience.

SITE AND GEOMATERIAL CHARACTERIZATION

The most valuable and reliable information for rock-socket design is obtained by drilling and taking core samples of the rock at the location of each structural foundation. Careful logging of rock core, photographic records, and proper handling of core to obtain samples for laboratory testing provide the basic information that will be used for rock mass classification, evaluation of engineering properties of intact rock

and rock mass, and baseline information needed to assess constructability. Drilling also provides the means to conduct in situ tests. Every transportation agency that responded to the survey currently relies on rock coring as the primary source of design and construction information for rock-socketed shafts.

Geophysical methods can provide additional valuable information when applied appropriately by competent users. *NCHRP Synthesis 357: Use of Geophysics for Transportation Projects* (Sirles) identifies the major geophysical methods that are applicable to geotechnical investigations and found that overall use of geophysics by transportation agencies is expanding. Seismic refraction for establishing depth to bedrock is the most common use of geophysics for drilled shafts in rock. However, of 33 responding agencies, only 8 (24%) reported using geophysics, including 7 that use seismic refraction and 1 that uses electrical resistivity. These data suggest that geophysical methods are not used widely for investigations related specifically to foundations in rock. Survey results from the Sirles study show that agency experience is mixed, with both successful and unsuccessful cases being cited. Factors associated with successful cases (for depth to bedrock) are: sufficient number of borings to validate and correlate the seismic results, interpretation by qualified geophysicists, and clear understanding of the capabilities and limitations of the technology.

Geophysical methods that show potential for rock site investigations include electrical resistivity tomographic profiling and borehole televiwers. Multi-array resistivity methods have shown the ability to provide accurate images of subsurface profiles in karstic terrains when used in conjunction with borings. Borehole televiwers, both acoustic and optical, may have limited applicability to rock foundations. They are primarily useful for providing detailed information on structural discontinuities. For large or critical rock-socket projects, where the orientation and condition of discontinuities in situ is a critical concern, these devices can supplement information obtained from more conventional core logging. Other potentially useful methods are downhole seismic and crosshole seismic. A case described by LaFronz et al. in 2004, "Geologic Characterization of Bridge Foundations, Colorado River Bridge, Hoover Dam Bypass Project," showed good correlation between rock mass modulus from downhole seismic testing and rock mass modulus from correlations to
