

COPD - emphysema

Emphysema is a chronic lung disease that causes the air sacs in the lungs to become damaged and inflamed. This leads to a loss of elasticity in the lung tissue, making it difficult to breathe. The condition is often associated with long-term smoking and can lead to a gradual decline in lung function over time.

Definition

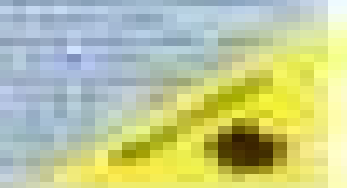

Emphysema is a chronic lung disease characterized by the destruction of the alveoli, the small air sacs in the lungs where gas exchange occurs. This leads to a loss of lung elasticity and an increase in lung volume, making it difficult to breathe. The condition is often associated with long-term smoking and can lead to a gradual decline in lung function over time.

Pathogenesis

The pathogenesis of emphysema involves a complex interplay of genetic and environmental factors. The most common cause is long-term exposure to cigarette smoke, which leads to the release of free radicals and inflammatory mediators that damage the lung tissue. Genetic factors, such as alpha-1 antitrypsin deficiency, can also contribute to the development of the disease. The process involves the destruction of the alveolar walls, leading to the formation of large, irregular air spaces and a loss of lung elasticity.

Diagnosis

Diagnosis of emphysema typically involves a combination of clinical history, physical examination, and imaging studies. A patient with a long history of smoking and symptoms such as chronic cough, sputum production, and shortness of breath may be suspected of having the disease. Physical examination may reveal hyperinflation of the lungs and decreased breath sounds. Imaging studies, such as chest X-rays and CT scans, can show characteristic changes in the lung architecture, including hyperinflation and destruction of the alveoli. Spirometry, a test that measures lung function, is also used to confirm the diagnosis and assess the severity of the disease.
