

## Activity 2.1.2 – Calculating Properties of Shapes

### Properties

If you were given the responsibility of painting a room, how would you know how much paint to purchase for the job? If you were told to purchase enough carpet to cover all the floors in your home, how would you know which carpet and design is required for the room? If you had to paint the walls in your dormitory, how would you determine the number of paint cans needed? Notice how the facts that each of these questions bases match those of engineering because they all center on the concept of area.

Area describes the measure of two-dimensional surfaces. One example of how area is used in engineering is the calculation of stress that develops in an object that is subjected to an external load. If you have ever watched an audience react to the point that it breaks, then you have applied an external load to an object that has a two-dimensional surface. As you can, you know stress is used to model the relationship between load and stress. Another example of how area is used in engineering is the calculation of beam deflections. If you have ever walked across a wooden beam in an effort to cross it safely, then you have experienced the concept of deflection. If the beam has a small deflection, then the amount of deflection was probably not small for that to occur.

### Equipment

- Member 2: pencil
- Calculator
- Engineer's notebook

### Procedure

In this activity, you will broaden your knowledge of shapes and your ability to calculate them. You will collect facts to calculate the dimensions and area of a shape. Use pencils, construction lines, and objects lines to sketch the shapes described in this handout and calculate them. Use the rules established in your engineer's notebook to draw the shapes (like necessary calculations). Calculate area for each shape, but you must show all of your work.
