

CALCULUS I

What Is Calculus

Calculus is the study of how things change. It provides a framework for modeling systems in which there is change, and a way to deduce the predictions of such models.

It provides a way for us to construct relatively simple quantitative models of change, and to deduce their consequences.

With this you get the ability to find the effects of changing conditions on the system being investigated. By studying these, you can learn how to control the system to do make it do what you want it to do. Calculus, by giving engineers and you the ability to model and control systems gives them (and potentially you) extraordinary power over the material world.

The development of calculus and its applications to physics and engineering is probably the most significant factor in the development of modern science beyond where it was in the days of Archimedes. And this was responsible for the industrial revolution and everything that has followed from it including almost all the major advances of the last few centuries.

The fundamental idea of calculus is to study change by studying "instantaneous" change, by which we mean changes over tiny intervals of time.

It turns out that such changes tend to be less simpler than changes over finite intervals of time. This means they are less easier to model. In fact calculus was invented by Newton, who discovered that acceleration, which means change of speed of objects could be modeled by his relatively simple laws of motion.

This leaves us with the problem of deducing information about the motion of objects from information about their

speed or acceleration. And the details of calculus involve the interrelations between the concepts exemplified by speed and acceleration and that represented by position.

What Is Functions

Functions are what we use to describe things we want to talk about mathematically. I find, though, that I get a bit tongue tied when I try to define them.

The simplest definition is: a function is a bunch of ordered pairs of things (in our case the things will be numbers, but they can be otherwise), with the property that the first members of the pairs are all different from one another.

Thus, here is an example of a function:

$\{(1, 1), (2, 1), (3, 2)\}$

This function consists of three pairs, whose first members are 1, 2 and 3.

It is customary to give functions names, like f , g or h , and if we call this function f , we generally use the following notation to describe it:

$f(1) = 1, f(2) = 1, f(3) = 2$

The first members of the pairs are called arguments and the whole set of them is called the domain of the function. Thus the arguments of f here are 1, 2 and 3, and the set consisting of these three numbers is its domain.

The second members of the pairs are called the values of the functions, and the set of these is called the range of the function.

The standard terminology for describing this function f is:

The value of f at argument 1 is 1, its value at argument 2 is 1, and its value at

argument 3 is 2, which we write as $f(1) = 1, f(2) = 1, f(3) = 2$.

We generally think of a function as a set of assignments of values (second members of our pairs) to arguments (their first members).

The condition that the first members of the pairs are all different is the condition that each argument in the domain of f is assigned a unique value in its range by any function.

Exercise: Consider the function g , defined by the pairs $(1, 1), (2, 2), (3, 1)$ and $(4, 2)$. What is its domain? What is the value of g at argument 3? What is $g(4)$?

If you stick a thermometer in your mouth, you can measure your temperature, at some particular time. You can define a function T or temperature, which assigns the temperature you measure to the time at which you remove the thermometer from your mouth. This is a typical function. Its arguments are times of measurement and its values are temperatures.

Of course your mouth has a temperature even when you don't measure it, and it has one at every instant of time and there are an infinite number of such instants.

This means that if you want to describe a function T whose value at any time t is the temperature in your mouth at that time, you cannot really list all its pairs. There are an infinite number of possible arguments t and it would take you forever to list them.

Instead, we employ a trick to describe a function f we generally provide a rule which allows you, the reader, to choose any argument you like in f 's domain, and, by using the rule, to compute the value of your function at that argument. This rule is often called a formula for the function. The symbol x is often used to denote the
