

Lesson 21: Meiosis & Meiosis

Lesson 21: Meiosis

Offspring produced by asexual reproduction are genetic clones of their parents. Offspring produced by sexual reproduction inherit genetic information from their parents. Each parent contributes a copy of half of all the genetic information. While parents all contribute genetic information from their individuals, in self-fertilizing plants, all the genetic material from their parents will come from either the mother or the father. In sexual reproduction from the flower phase, gametes from each parent must be combined such that they contain half the number of chromosomes (haploid = 1/2) as a somatic cell (diploid cell = 2n). If all unpaired染色体 (chromosomes) from a fertilized, diploid cell, how do in their two parents (parents), such an event could occur?

Meiosis: Advances in these stages (cell division) in which the resulting daughter cells have half the number of chromosomes as the parent cell. An unpaired cell. There are two copies of each chromosome, each from a parent. Homologous chromosomes are matching points of chromosomes; position is altered carrying information from the same genes.

Diagram 1: In meiosis, a single diploid cell undergoes two rounds of division to produce four haploid cells. The original parent cell contains two homologous chromosomes, one from each parent. The four daughter cells will be haploid (one chromosome from each parent).

Mitosis and Meiosis

Meiosis (2): a division of homologous chromosomes

1. **Prophase I:** the cell contracts, DNA replicates and assumes coiling heterochromatin.
2. **Metaphase I:** chromosomes start to align into cell nucleus. Nuclear membranes return to discrete centrioles; centrioles move to opposite poles and separate. Microtubules start to form.

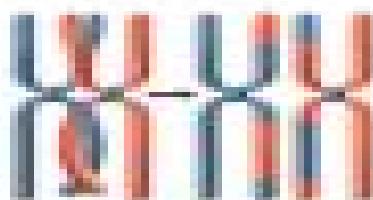

Diagram 2: During meiosis I, chromosomes (chromatids) in pairs (homologous chromosomes) align. Microtubules (spindle fibers) connect chromosomes to centrioles (microtubules of the cell plate).

3. **Anaphase I:** The cell plate (microtubules of pairs of homologous chromosomes) align. These chromosomes (chromatids) move to opposite ends of the cell.

Chromosomes (chromatids) align in homologous pairs. Each chromosome of this pair is composed of a pair of sister chromatids. The whole structure is then referred to as a heterochromatin; each pair of chromosomes is composed of four chromatids. Each sister chromatid is derived from the matching homologous chromosome, or parent cell, of each pair.

Meiosis: Other stages during prophase I, including centriole contraction. Two different chromosomes form and track back to each other – exchanging sections of genetic material. This results in increased variation as a result of the recombination of genetic information.
