### **Stability of Solutions to Convex Problems of Optimization** K. Malanowski, 2014-03-12      [Convex Optimization with Computational Errors](#) Alexander J. Zaslavski, 2020-01-31

The book is devoted to the study of approximate solutions of optimization problems in the presence of computational errors It contains a number of results on the convergence behavior of algorithms in a Hilbert space which are known as important tools for solving optimization problems The research presented in the book is the continuation and the further development of the author's c 2016 book Numerical Optimization with Computational Errors Springer 2016 Both books study the algorithms taking into account computational errors which are always present in practice The main goal is for a known computational error to find out what an approximate solution can be obtained and how many iterates one needs for this The main difference between this new book and the 2016 book is that in this present book the discussion takes into consideration the fact that for every algorithm its iteration consists of several steps and that computational errors for different steps are generally different This fact which was not taken into account in the previous book is indeed important in practice For example the subgradient projection algorithm consists of two steps The first step is a calculation of a subgradient of the objective function while in the second one we calculate a projection on the feasible set In each of these two steps there is a computational error and these two computational errors are different in general It may happen that the feasible set is simple and the objective function is complicated As a result the computational error made when one calculates the projection is essentially smaller than the computational error of the calculation of the subgradient Clearly an opposite case is possible too Another feature of this book is a study of a number of important

algorithms which appeared recently in the literature and which are not discussed in the previous book This monograph contains 12 chapters Chapter 1 is an introduction In Chapter 2 we study the subgradient projection algorithm for minimization of convex and nonsmooth functions We generalize the results of NOCE and establish results which has no prototype in NOCE In Chapter 3 we analyze the mirror descent algorithm for minimization of convex and nonsmooth functions under the presence of computational errors For this algorithm each iteration consists of two steps The first step is a calculation of a subgradient of the objective function while in the second one we solve an auxiliary minimization problem on the set of feasible points In each of these two steps there is a computational error We generalize the results of NOCE and establish results which has no prototype in NOCE In Chapter 4 we analyze the projected gradient algorithm with a smooth objective function under the presence of computational errors In Chapter 5 we consider an algorithm which is an extension of the projection gradient algorithm used for solving linear inverse problems arising in signal image processing In Chapter 6 we study continuous subgradient method and continuous subgradient projection algorithm for minimization of convex nonsmooth functions and for computing the saddle points of convex concave functions under the presence of computational errors All the results of this chapter has no prototype in NOCE In Chapters 7 12 we analyze several algorithms under the presence of computational errors which were not considered in NOCE Again each step of an iteration has a computational errors and we take into account that these errors are in general different An optimization problems with a composite objective function is studied in Chapter 7 A zero sum game with two players is considered in Chapter 8 A predicted decrease approximation based method is used in Chapter 9 for constrained convex optimization Chapter 10 is devoted to minimization of quasiconvex functions Minimization of sharp weakly convex functions is discussed in Chapter 11 Chapter 12 is devoted to a generalized projected subgradient method for minimization of a convex function over a set which is not necessarily convex The book is of interest for researchers and engineers working in optimization It also can be useful in preparation courses for graduate students The main feature of the book which appeals specifically to this audience is the study of the influence of computational errors for several important optimization algorithms The book is of interest for experts in applications of optimization to engineering and economics

*Convex Optimization & Euclidean Distance Geometry* Jon Dattorro, 2005. The study of Euclidean distance matrices (EDMs) fundamentally asks what can be known geometrically given only distance information between points in Euclidean space. Each point may represent simply location or abstractly any entity expressible as a vector in finite dimensional Euclidean space. The answer to the question posed is that very much can be known about the points. The mathematics of this combined study of geometry and optimization is rich and deep. Throughout we cite beacons of historical accomplishment. The application of EDMs has already proven invaluable in discerning biological molecular conformation. The emerging practice of localization in wireless sensor networks, the global positioning system (GPS), and distance based pattern recognition will certainly simplify and benefit from this theory. We study the pervasive convex Euclidean bodies and their various representations. In particular, we make convex polyhedra, cones, and dual cones more visceral through illustration, and we study the geometric relation of polyhedral cones to nonorthogonal bases, biorthogonal expansion. We explain conversion between halfspace and vertex descriptions of convex cones; we provide formulae for determining dual cones, and we show how classic alternative systems of linear inequalities or linear matrix inequalities and optimality conditions can be explained by generalized inequalities in terms of convex cones and their duals. The conic analogue to linear independence called conic independence is introduced as a new tool in the study of classical cone theory, the logical next step in the progression linear, affine, conic. Any convex optimization problem has geometric interpretation. This is a powerful attraction: the ability to visualize geometry of an optimization problem. We provide tools to make visualization easier. The concept of faces, extreme points, and extreme directions of convex Euclidean bodies is explained here, crucial to understanding convex optimization. The convex cone of positive semidefinite matrices, in particular, is studied in depth. We mathematically interpret, for example, its inverse image under affine transformation, and we explain how higher rank subsets of its boundary, united with its interior, are convex. The Chapter on Geometry of convex functions observes analogies between convex sets and functions. The set of all vector valued convex functions is a closed convex cone. Included among the examples in this chapter, we show how the real affine function relates to convex functions as the hyperplane relates to convex sets. Here also, pertinent results for multidimensional convex functions are presented that are largely ignored in the literature, tricks and tips for determining their convexity, and discerning their geometry, particularly with regard to matrix calculus, which remains largely unsystematized when compared with the traditional practice of ordinary calculus. Consequently, we collect some results of matrix differentiation in the appendices. The Euclidean distance matrix (EDM) is studied, its properties, and relationship to both positive semidefinite and Gram matrices. We relate the EDM to the four

classical axioms of the Euclidean metric thereby observing the existence of an infinity of axioms of the Euclidean metric beyond the triangle inequality. We proceed by deriving the fifth Euclidean axiom and then explain why furthering this endeavor is inefficient because the ensuing criteria while describing polyhedra grow linearly in complexity and number. Some geometrical problems solvable via EDMs. EDM problems posed as convex optimization and methods of solution are presented. eg we generate a recognizable isotonic map of the United States using only comparative distance information no distance information only distance inequalities. We offer a new proof of the classic Schoenberg criterion that determines whether a candidate matrix is an EDM. Our proof relies on fundamental geometry assuming any EDM must correspond to a list of points contained in some polyhedron possibly at its vertices and vice versa. It is not widely known that the Schoenberg criterion implies nonnegativity of the EDM entries proved here. We characterize the eigenvalues of an EDM matrix and then devise a polyhedral cone required for determining membership of a candidate matrix in Cayley Menger form to the convex cone of Euclidean distance matrices. EDM cone ie a candidate is an EDM if and only if its eigenspectrum belongs to a spectral cone for EDM  $N$ . We will see spectral cones are not unique. In the chapter EDM cone we explain the geometric relationship between the EDM cone two positive semidefinite cones and the elliptope. We illustrate geometric requirements in particular for projection of a candidate matrix on a positive semidefinite cone that establish its membership to the EDM cone. The faces of the EDM cone are described but still open is the question whether all its faces are exposed as they are for the positive semidefinite cone. The classic Schoenberg criterion relating EDM and positive semidefinite cones is revealed to be a discretized membership relation a generalized inequality a new Farkas like lemma between the EDM cone and its ordinary dual. A matrix criterion for membership to the dual EDM cone is derived that is simpler than the Schoenberg criterion. We derive a new concise expression for the EDM cone and its dual involving two subspaces and a positive semidefinite cone. Semidefinite programming is reviewed with particular attention to optimality conditions of prototypical primal and dual conic programs their interplay and the perturbation method of rank reduction of optimal solutions extant but not well known. We show how to solve a ubiquitous platonic combinatorial optimization problem from linear algebra the optimal Boolean solution  $x$  to  $Ax \leq b$  via semidefinite program relaxation. A three dimensional polyhedral analogue for the positive semidefinite cone of  $3 \times 3$  symmetric matrices is introduced a tool for visualizing in 6 dimensions. In EDM proximity we explore methods of solution to a few fundamental and prevalent Euclidean distance matrix proximity problems the problem of finding that Euclidean distance matrix closest to a given matrix in the Euclidean sense. We pay particular attention to the problem when compounded with rank minimization. We offer a new geometrical proof of a famous result discovered by Eckart Young in 1936 regarding Euclidean projection of a point on a subset of the positive semidefinite cone comprising all positive semidefinite matrices having rank not exceeding a prescribed limit  $\rho$ . We explain how this problem is transformed to a convex optimization for any rank  $\rho$ .

**Introductory Lectures on Convex Optimization** Yurii Nesterov, 2003-12-31 It was in the middle of the 1980s when the seminal paper by Kar markar opened a new epoch in nonlinear optimization The importance of this paper containing a new polynomial time algorithm for linear optimization problems was not only in its complexity bound At that time the most surprising feature of this algorithm was that the theoretical prediction of its high efficiency was supported by excellent computational results This unusual fact dramatically changed the style and directions of the research in nonlinear optimization Thereafter it became more and more common that the new methods were provided with a complexity analysis which was considered a better justification of their efficiency than computational experiments In a new rapidly developing field which got the name polynomial time interior point methods such a justification was obligatory After almost fifteen years of intensive research the main results of this development started to appear in monographs 12 14 16 17 18 19 Approximately at that time the author was asked to prepare a new course on nonlinear optimization for graduate students The idea was to create a course which would reflect the new developments in the field Actually this was a major challenge At the time only the theory of interior point methods for linear optimization was polished enough to be explained to students The general theory of self concordant functions had appeared in print only once in the form of research monograph 12

dimensions and the analytical geometrical foundations of convex optimization and duality theory Convexity theory is first developed in a simple accessible manner using easily visualized proofs Then the focus shifts to a transparent geometrical line of analysis to develop the fundamental duality between descriptions of convex functions in terms of points and in terms of hyperplanes Finally convexity theory and abstract duality are applied to problems of constrained optimization Fenchel and conic duality and game theory to develop the sharpest possible duality results within a highly visual geometric framework This on line version of the book includes an extensive set of theoretical problems with detailed high quality solutions which significantly extend the range and value of the book The book may be used as a text for a theoretical convex optimization course the author has taught several variants of such a course at MIT and elsewhere over the last ten years It may also be used as a supplementary source for nonlinear programming classes and as a theoretical foundation for classes focused on convex optimization models rather than theory It is an excellent supplement to several of our books Convex Optimization Algorithms Athena Scientific 2015 Nonlinear Programming Athena Scientific 2017 Network Optimization Athena Scientific 1998 Introduction to Linear Optimization Athena Scientific 1997 and Network Flows and Monotropic Optimization Athena Scientific 1998

The Projected Subgradient Algorithm in Convex Optimization Alexander J. Zaslavski, 2020-11-25 This focused monograph presents a study of subgradient algorithms for constrained minimization problems in a Hilbert space The book is of interest for experts in applications of optimization to engineering and economics The goal is to obtain a good approximate solution of the problem in the presence of computational errors The discussion takes into consideration the fact that for every algorithm its iteration consists of several steps and that computational errors for different steps are different in general The book is especially useful for the reader because it contains solutions to a number of difficult and interesting problems in the numerical optimization The subgradient projection algorithm is one of the most important tools in optimization theory and its applications An optimization problem is described by an objective function and a set of feasible points For this algorithm each iteration consists of two steps The first step requires a calculation of a subgradient of the objective function the second requires a calculation of a projection on the feasible set The computational errors in each of these two steps are different This book shows that the algorithm discussed generates a good approximate solution if all the computational errors are bounded from above by a small positive constant Moreover if computational errors for the two steps of the algorithm are known one discovers an approximate solution and how many iterations one needs for this In addition to their mathematical interest the generalizations considered in this book have a significant practical meaning
